Reliability of the Italian version of the Brief (21-item) Prodromal Questionnaire (IPQ-B) for psychosis risk screening in a young help-seeking population

Summary

Objective
Among current screeners for psychosis-risk mental states, the Prodromal Questionnaire-Brief (21 items) (PQ-B) is used. We aimed to assess reliability of the Italian version of the PQ-B in a young help-seeking sample. Methods – We included 151 individuals, aged 13-35 years, seeking help at the Reggio Emilia outpatient mental health services in a large semirural catchment area (550,000 inhabitants). Participants completed the Italian version of the PQ-B (iPQ-B) and were subsequently evaluated with the Comprehensive Assessment of At-Risk Mental States (CAARMS). We examined test-retest reliability, internal consistency and diagnostic accuracy (i.e. sensitivity, specificity, positive and negative predictive values, and positive and negative likelihood ratios) between PQ-B and CAARMS UHR-defined criteria using coefficient of stability (k), Cronbach’s alpha and Cohen’s kappa, respectively.

Results
The iPQ-B showed excellent short term test-retest reliability (k = 0.891), high internal consistency (α = 0.876) and acceptable diagnostic accuracy (sensitivity = 91.4% at the proposed cut-off of ≥ 6 on total distress score).

Conclusions
Psychometric properties of the iPQ-B were satisfactory. The iPQ-B is a suitable screening tool for routine use in mental health care services. Indeed, it is short and therefore easy to implement in routine assessment of early psychosis.

Key words
Ultra-High Risk • Prodrome • Early Detection • Screening • Psychosis • Schizophrenia • Assessment

Introduction
Specialist treatment for Ultra-High Risk (UHR) mental states of psychotic disorders can effectively reduce psychosis conversion rate 1. However, identifying individuals with UHR remains a significant challenge 2. Focusing mainly on attenuated positive symptoms, McGorry et al. (2003) 3 proposed the following UHR criteria: (a) Attenuated Psychotic Symptoms (APS), which represent subthreshold positive symptoms; (b) Brief Limited Intermittent Psychotic Symptoms (BLIPS), which are transient positive symptoms that spontaneously disappear within 1 week; and (c) Genetic Risk and Functioning Deterioration syndrome (GRFD), a trait/state risk condition characterized by a history of psychosis in first-degree family members or a schizotypal personality disorder in the subject together with a low functioning for at least 1 month 4. Translating the early detection/intervention research framework into clinical care pathways relies, in part, on the recognition of these young people at the earliest point in their help-seeking trajectory 5 6.
Although structured interviews, such as the Comprehensive Assessment of At-Risk Mental States (CAARMS) \(^4\) or the Structured Interview for Prodromal States (SIPS) \(^7\), can reliably diagnose UHR states \(^8\), they generally require extensive training to be administered and can take hours to be completed \(^9\). Therefore, an array of self-report screening tools has been developed to preselect potential UHR individuals for subsequent in-depth clinical assessment \(^10\). Accumulating empirical evidence suggests that these self-report instruments are sufficiently sensitive and specific to detect the majority of those subjects that merit a more comprehensive evaluation for UHR or First-Episode Psychosis (FEP) \(^11\). The 92-item Prodromal Questionnaire (PQ-92) \(^12\) is the most commonly used screener for psychosis risk in the literature \(^10\). However, this instrument remains rather time-consuming for routine screening \(^9\). Thus, Loewy et al. (2011) \(^13\) developed a Brief 21-item version (PQ-B), focusing on the positive symptom items of the PQ-92, since they are the essential ones for interview-based diagnoses of symptomatic prodromal syndromes (i.e. APS and BLIPS). A cut-off of \(\geq 6\) on the PQ-B total distress score predicted SIPS-UHR/psychosis diagnosis with high sensitivity (88\%) and good specificity (68\%) \(^13\).

Overall, early intervention in young people at UHR for developing psychosis are less widespread in Italy than in other European countries \(^14\). In particular, some pilot programmes have focused specifically on early detection and intervention in UHR young adults, aged 18-30 years (see Cocchi et al., 2008: “Programma 2000”) \(^15\).

Therefore, translating an easy and suitable self-report screening instrument (such as the PQ-B) into Italian language could lead to the implementation of specific services for UHR individuals within the framework of Italy’s National Health Service. To the best of our knowledge, no psychometric evaluation study on the PQ-B in an Italian clinical sample has been reported in the literature to date. Thus, the current study was designed to test the reliability of the Italian version of the PQ-B (iPQ-B) in identifying young people at UHR of psychosis in a help-seeking community population.

Materials and methods

Setting

As detailed in Raballo et al. (2014) \(^16\), the “Reggio Emilia At-Risk Mental States” (ReARMS) project is an early detection/intervention infrastructure implemented under the aegis of the “Regional Project on Early Detection and Intervention in Psychosis” in the Reggio Emilia Department of Mental Health. This project aims: (a) to identify people with FEP and individuals at high clinical risk according to UHR criteria \(^4\) among help-seeking adolescents and young adults (13-35 years) through a multi-step procedure, and (b) to provide evidence-based interventions that are supposed to be effective in UHR/FEP subjects (i.e. intensive case management, family psycho-education, individual cognitive-behavioral therapy, pharmacological treatment [as appropriate]). The first filtering step included a pre-clinical triage service, conducted by trained non-medical personnel, using the “Screening Schedule” for Psychosis (SS) \(^17\). Such triage was mainly meant to maximise appropriate referrals to the ReARMS project and avoid over-inclusion of subjects clearly outside the severity threshold for presumed psychosis risk spectrum. The second step included a comprehensive multidimensional battery including the iPQ-B, followed by the administration of the CAARMS to define the clinical status (i.e. psychosis risk, psychosis, or neither) and the consequent access to the ReARMS clinical-therapeutic pathways \(^16\). Complying with the declaration of Helsinki, relevant ethical approvals were locally sought for the study.

Participants

For the purpose of the study (i.e. field-testing the reliability of the iPQ-B in identifying UHR mental states), we focused on adolescent and young adult help-seekers, aged 13-35 years, who were consecutively referred to all of child/adolescent and adult mental health services of the Reggio Emilia Department of Mental Health between September 2012 and September 2017. In the present research, inclusion criteria were: (a) specialist help-seeking; (b) age between 13 and 35 years; and (c) presence of UHR criteria defined by the CAARMS (i.e. APS, BLIPS, and/or GRFD) \(^4\) at the initial assessment. Individuals who were below the CAARMS UHR threshold were considered as CAARMS-UHR negative cases. The exclusion criteria were modeled on the psychometric approach adopted by Loewy et al. (2011) \(^13\) in the validation study of the original version of the PQ-B: (a) history of past frank psychotic episodes, either affective or schizophrenic (as described in the DSM-5) \(^16\); (b) history of previous exposure to antipsychotics; (c) current substance dependence; (d) severe learning disability or known mental retardation (Intelligence Quotient < 70); (e) neurological disease or any other medical disorder associated with psychiatric symptoms; (f) poor fluency in the Italian language; and (g) residence outside the catchment area. All these exclusion criteria have been applied after the SS administration in order to select a sample comparable to one assessed by Loewy et al. (2011) \(^13\).

All help-seekers entering the ReARMS project agreed to participate to the research and gave their informed consent to the psychopathological evaluation, composed – among others \(^16\) – by the CAARMS (approved Italian translation by Raballo et al., 2013 [CAARMS-ITA]) \(^19\) and the PQ-B (authorized Italian version by Preti and Rabal-
Per cortesia, indica se hai avuto i seguenti pensieri, sentimenti ed esperienze nel corso dell’ultimo mese segnando “Sì” o “No” per ciascuna domanda. Non tenere conto di esperienze che si verificano sotto influenza di alcol, droghe o farmaci che non ti erano stati prescritti. Se rispondi “Sì” a una domanda indica anche quanto disagio ti ha causato quell’esperienza [quanto spiacevole è stata per te quell’esperienza].

1. Capita talvolta che gli ambienti abituali ti sembrino strani, confusi, minacciosi o irreali?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

2. Hai mai sentito suoni insoliti come esplosioni, schiocchi, sibili, schianti o squilli nelle tue orecchie?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

3. Le cose che vedi ti appaiono differenti dal modo in cui sono abitualmente (più luminose o più scure, più larghe o più piccole, comunque cambiate in qualche modo)?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

4. Hai avuto esperienze con la telepatia, le forze psichiche o la predizione del futuro?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

5. Ti sei sentito come se non avessi controllo sulle tue idee o pensieri?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

6. Hai difficoltà a spiegarti, perché fai troppe digressioni o devi dal filo del discorso quando parli?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

7. Hai l’impressione o la convinzione di essere dotato in modo particolare o di possedere un talento speciale?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

8. Hai l’impressione che altre persone ti stiano tenendo d’occhio o parlino di te?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo ☐ Indifferente ☐ D’accordo ☐ Fortemente d’accordo

9. Hai talvolta sensazioni strane sulla pelle o appena al di sotto, come insetti che camminano?
   ☐ SI ☐ NO Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi: ☐ Fortemente in disaccordo ☐ In disaccordo

Appendix I

The Italian version of the Brief (21-item) Prodromal Questionnaire (iPQ-B)

(Authorized Italian version by Preti A, Raballo A. Studio CAPIRE. Cagliari Psychosis: Investigation on Risk Emergence, 2011).

I. Scazza et al.

lo, 2011 [iPQ-B]) (Appendix I). While in chronological terms the iPQ-B was administered after the SS for psychosis, the meaning of its administration was different (i.e. zooming in on prodromal experiences before the CAARMS-based interview) and the CAARMS assessors were blinded to the iPQ-B scores.
10. Ti capita talvolta di essere distratto all’improvviso da suoni distanti dei quali generalmente non sei consapevole? [ai quali normalmente non presti attenzione]
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

11. Hai la sensazione che qualche persona o forza ti stia accanto anche se tu non puoi vederla?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

12. Ti preoccupi talvolta del fatto che qualcosa nella tua mente non funzioni correttamente?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

13. Hai mai avuto la sensazione di non esistere, o che il mondo non esiste, o di essere morto?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

14. Qualche volta ti sei sentito confuso sulla natura reale o immaginaria di un’esperienza?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

15. Hai delle idee o delle convinzioni che altre persone troverebbero insolite o bizzarre?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

16. Senti che parti del tuo corpo sono cambiate in qualche modo, o che funzionano in modo diverso?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

17. I tuoi pensieri sono talvolta così forti che puoi quasi udirli?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

18. Ti capita di provare sfiducia o essere sospettoso riguardo alle altre persone?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

19. Hai visto oggetti insoliti come bagliori, fiamme, lampi accenanti o figure geometriche?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

20. Hai visto cose che altri non riescono a vedere o non sembrano notare?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

21. Capita talvolta che le persone abbiano difficoltà a capire quello che stai dicendo?
   - SI
   - NO
   - Se Sì: Quando capita, mi sento spaventato, preoccupato, o comunque la cosa mi crea problemi:
     - Fortemente in disaccordo
     - In disaccordo
   - Indifferente
   - D’accordo
   - Fortemente in disaccordo

Measures
The CAARMS is a semi-structured clinical interview designed to cover different aspects of attenuated psychopathology as well as functioning (via the integrated Social and Occupational Functioning Assessment Scale [SOFAS] module). It takes approximately 1-1.5 hours to be administered and consists of 27 items (each one scored in terms of frequency/duration [0-6] and intensity [0-6]). Those items are clustered in seven subscales: (a) “Positive Symptoms”, (b) “Cognitive Change, Atten-
tion and Concentration”, (c) “Emotional Disturbance”, (d) “Negative Symptoms”, (e) “Behavioral Change”, (f) “Motor/Physical Changes”, and (g) “General Psychopathology”. The CAARMS “Positive Symptoms” subscale, which covers delusions, hallucinations and thought disorder, is used to determine the UHR criteria. UHR status is defined as follows: (a) GRFD group: schizotypal personality disorder in the subject or history of psychosis in a first-degree family member associated with 30% drop in functioning for ≤ 1 month or chronic low functioning (the decline in functioning is estimated by subtracting the current SOFAS score from the highest SOFAS score in the past year); (b) APS group: sub-threshold positive psychotic symptoms within the past 12 months; and (c) BLIPS group: criteria for psychotic disorder met for < 7 day and remitting spontaneously (i.e. without antipsychotic medication).

CAARMS interviews are conducted by specialized personnel including clinical psychologists and psychiatrists, who underwent collective supervision by the main author of the approved Italian translation, who was trained at Orygen, the National Youth Research Center in Melbourne, Australia. The inter-rater reliability of these assessments was ensured by regular CAARMS scoring workshops and supervision sessions.

The PQ-B13 is a self-report questionnaire used to screen individuals for the risk of psychosis. It only takes approximately 4 minutes to be completed and comprises of 21 items recording positive symptoms experienced over the past month. For each endorsed symptom, responders rate whether they found it distressing or impairing, ranging from 1 (“strongly disagree”) to 5 (“strongly agree”), with a 4 or 5 indicating distress. The PQ-B has been adopted as a screening tool using the total distress score (range 0-105), with the latter representing the coefficient of stability within the total sample. A score above 0.65 interpreted test-retest reliability coefficients as follows: ≥ 0.90 excellent reliability, 0.81-0.90 good reliability, 0.71-0.80 acceptable reliability, 0.61-0.70 questionable reliability, 0.51-0.60 poor reliability, and ≤ 0.50 unacceptable reliability.

Moreover, we examined long-term test-retest reliability of the iPQ-B calculating the coefficient of stability within all the participants who had scored ≥ 6 on the iPQ-B total distress score at the initial assessment (n = 123). As additional measure of reliability, the internal consistency of the iPQ-B was assessed using Cronbach’s α statistics within the total sample. A score above 0.65 represented a sufficient internal consistency. We also examined how each PQ-B item correlated with the recommended total score (i.e. the total distress score). Correlations less than r = 0.30 indicated that the item might need to be removed from the questionnaire to make it more reliable. Finally, we were interested in Cronbach’s alpha value if each iPQ-B item was deleted. If this score went up after item deletion, removal should be considered to ameliorate screening tool reliability of the instrument. Furthermore, we investigated the concurrent validity of the iPQ-B by comparing its results to CAARMS outcomes. In the total sample, we examined diagnostic accuracy of ≥ 3 symptoms endorsed was supported, whereas in a lower prevalence sample from a similar setting, a higher threshold of ≥ 9 was identified (albeit below 75% sensitivity).
measures (i.e. sensitivity, specificity, positive and negative predictive values [PPV and NPV], and positive and negative likelihood ratios [LR+ and LR-], that balance sensitivity against specificity). As an additional measure of concurrent validity, the correspondence of positive results on the iPQ-B (i.e. a total distress score ≥ 6 or, as alternatives, the recommended symptom total score ≥ 3 or item distressing total score ≥ 4) and on the CAARMS (i.e. a score ≥ 3 on at least one positive symptom item) was also examined by Cohen's kappa statistics.

Finally, to explore which iPQ-B items were likely to be more predictive of CAARMS UHR diagnosis, we employed a forward stepwise logistic regression analysis, with iPQ-B item scores as independent variables and dichotomized CAARMS diagnoses (i.e. UHR- vs UHR+) as dependent variable.

**Results**

Over the course of the study, 151 individuals (79 females and 72 males; mean age ± Standard Deviation [SD] = 20.00 ± 5.78) consecutively participated at the intake interview within the ReARMS protocol. Table I shows screening outcomes and demographic characteristics of the total sample and the two subgroups, i.e. UHR+ (n = 70) and UHR- (n = 81). No significant differences were found in terms of gender, ethnic group, mother tongue, age, years of education, and Duration of Untreated Illness (DUI) [6].

In comparison with UHR-, UHR+ individuals showed significantly higher iPQ-B scores (Tab. I). To calculate short-term test-retest reliability, the iPQ-B was re-administered to 15 participants who had scored ≥ 6 on total distress score at the first assessment. Their socio-demographic characteristics were comparable to those of the total sample, with a mean age of 19.94 years and a SD of 4.89 years. Eight (53%) participants were females. The coefficient of stability was 0.891 for iPQ-B total distress score, indicating good to excellent short-term test-retest reliability [26].

To examine long-term test-retest reliability, the iPQ-B was administered over 1 year to 123 individuals who had scored ≥ 6 on total distress score at the baseline. Their demographic features were comparable to those of the entire sample, with a mean age of 20.10 years and a SD of 5.01 years. Sixty-three (51.2%) subjects were females. The coefficient of stability was 0.395, indicating unacceptable long-term test-retest reliability [26].

Across the total sample, the iPQ-B total distress score showed a Cronbach’s alpha of 0.876. All item-total correlations were higher than 0.30, with the exception of item 9 (“Do you sometimes get strange feelings on or just beneath your skin, like bugs crawling?”) (r = 0.213) (Tab. II). Therefore, most item appeared to be worthy of retention, resulting in a decrease in the alpha if deleted. Exception to this was item 9, whose deletion increased Cronbach’s alpha up to the value of 0.879. Thus, removal of this item can be considered.

* p < 0.001.

Frequencies and percentages, mean (standard deviation), chi-squared (χ²) test (with Yates correction), Student’s t test, and Mann-Whitney U test (Z) values are reported.
At the proposed PQ-B total distress score cut-off of ≥ 613, 125 participants (82.7%) scored positive; of these, 64 (50.4%) also scored ≥ 3 on any positive CAARMS item (i.e. meeting the UHR threshold). Altogether, 6 participants (8.6%) with any CAARMS positive score ≥ 3 were missed by this PQ-16 cut-off, and 61 (49.6%) were falsely identified. Cohen's kappa was 0.141, consistent with a slight agreement.\(^{29}\) With regard to the diagnostic accuracy at the proposed PQ-B cut-off of ≥ 6 on total distress score, sensitivity was 91.4%, specificity 24.7%, PPV 51.2%, NPV 79.3%, LR+ 1.28, LR- 0.35. Thus, at this threshold, the iPQ-B total distress score was slightly better in ruling out than in ruling in possible UHR status, changing post-test probability to a small (but sometimes important) degree.\(^{30}\) Considering the proposed PQ-B cut-off of ≥ 3 on symptom total score\(^{13}\), sensitivity was 91.4%, specificity 28.4%, PPV 52.4%, NPV 79.3%, LR+ 1.28, LR- 0.30, and Cohen's kappa 0.177. Finally, examining the diagnostic accuracy measures of the recommended PQ-B cut-off threshold of ≥ 4 on distressing item total score\(^{21}\), sensitivity was 61.4%, specificity 75.3%, PPV 68.2%, NPV 69.3%, LR+ 1.89, LR- 0.51, and Cohen's kappa 0.356 (consistent with a fair agreement).\(^{29}\)

Using a conditional forward stepwise method, five items (iPQ-B5, iPQ-B6, iPQ-B8, iPQ-B9, and iPQ-B13) were entered into the regression model with a statistically significant power (Tab. III). Although iPQ-B 5, 6, 8, and 13 had

iPQ-B: Italian Prodromal Questionnaire-Brief version.
Correlation r coefficients and Cronbach's alpha values are reported.
Reliability of the Italian version of the Brief (21-item) Prodromal Questionnaire (iPQ-B) for psychosis risk screening

Loewy et al. (2011) found an excellent PQ-B internal consistency with a Cronbach’s alpha of 0.853. Moreover, Xu et al. (2016) showed an overlapping internal consistency (α = 0.897) in Chinese help-seeking individuals (aged 15-45 years) visiting a general mental health setting. Therefore, PQ-B appears to be reliably good in different samples and cultures. Moreover, in our sample, iPQ-B demonstrated a Cronbach’s alpha value that we consider as satisfactory internal consistency for a screener that has to come before a clinical interview.

In a recent validation study of the Italian version of the PQ-92, Kotzalidis et al. (2017) re-administered the instrument to 15 individuals two weeks after first assessment and found excellent short-term test-retest reliability (coefficient of stability = 0.942 for PQ-92 total score). Similarly, we found a coefficient of stability equal to 0.891, indicating a good to excellent short-term (two-week) test-retest reliability of the iPQ-B.

Based on what Kotzalidis et al. (2017) suggested, we also addressed longer term test-retest reliability administering the iPQ-B over 1 year to all the participants who had scored ≥ 6 on total distress score at first assessment. We found a coefficient of stability = 0.395, indicating unacceptable long-term test-retest reliability.

According to Michel et al. (2014), this finding suggests that the self-report screening questionnaire assessed a fluctuating condition rather than a trait characteristic, i.e., a condition itself that varied between test and retest. When examining these results, some methodological peculiarities of the current study shall be considered. Indeed, ReARMS is a clinically project providing evidence-based interventions that are supposed to be effective in UHR individuals (i.e., intensive positive regression coefficients, iPQ-B 9 showed a negative one. The percentage of correct diagnosis using this model for predicting CAARMS UHR diagnosis was 76.7%.

iPQ-B: Italian Prodromal Questionnaire – Brief version, CAARMS: Comprehensive Assessment of At-Risk Mental States; UHR: Ultra-High Risk mental states; B: regression coefficient; SE: standard error; Wald: Wald statistic value; df: degree of freedom; p: statistical significance; and OR: odd ratio

Discussion

Aim of the current was to evaluate the reliability of PQ-B in an Italian clinical sample of young people at UHR of psychosis. Introducing and promoting the routine use of the Italian version of a validated assessment tool to detect UHR subjects in the general help-seeking population (such as the iPQ-B) could positively impact on the implementation of specific services for early detection and intervention on UHR individuals within the framework of Italy’s National Health Service. In the current study, we therefore examined test-retest reliability and internal consistency of the iPQ-B in consecutive young help-seekers attending all of child/adolescent and adult mental health services of the Reggio Emilia Department of Mental Health.

In comparison with UHR-, UHR+ individuals showed significantly higher iPQ-B total scores. On a dimensional level – as expected on the basis of the PQ-B item composition - these findings suggest that increasing PQ-B scores are associated with the severity of both psychotic and general psychopathology, as well as the intensity of distress related to prodromal symptoms.

We found excellent reliability of the iPQ-B with regard to internal consistency of the total distress score (α = 0.876). Removal of item 9 (“Do you sometimes get strange feelings on or just beneath your skin, like bugs crawling?”), which resulted in a slight increase in Cronbach’s alpha value up to 0.879, can be considered. Similarly, in a comparable adolescent/young adult help-seeking sample (age between 12 and 35 years), Loewy et al. (2011) found an excellent PQ-B internal consistency with a Cronbach’s alpha of 0.853. Moreover, Xu et al. (2016) showed an overlapping internal consistency (α = 0.897) in Chinese help-seeking individuals (aged 15-45 years) visiting a general mental health setting. Therefore, PQ-B appears to be reliably good in different samples and cultures. Moreover, in our sample, iPQ-B demonstrated a Cronbach’s alpha value that we consider as satisfactory internal consistency for a screener that has to come before a clinical interview.

In a recent validation study of the Italian version of the PQ-92, Kotzalidis et al. (2017) re-administered the instrument to 15 individuals two weeks after first assessment and found excellent short-term test-retest reliability (coefficient of stability = 0.942 for PQ-92 total score). Similarly, we found a coefficient of stability equal to 0.891, indicating a good to excellent short-term (two-week) test-retest reliability of the iPQ-B.

Based on what Kotzalidis et al. (2017) suggested, we also addressed longer term test-retest reliability administering the iPQ-B over 1 year to all the participants who had scored ≥ 6 on total distress score at first assessment. We found a coefficient of stability = 0.395, indicating unacceptable long-term test-retest reliability.
case-management, family psycho-education, individual cognitive-behavioral therapy within the framework of assertive community treatment). Precisely because providing the optimal treatment for the help-seekers was the main ethical mandate in our clinical setting, our treatments were not controlled (e.g. against placebo group or other treatments), but evenly delivered to all UHR participants.

In the original study validating the PQ-B, Loewy et al. (2011) observed a good to excellent concurrent validity with CAARMS diagnoses in a sample of adolescent and young adult help-seeking attending to an Early Intervention Psychosis (EIP) service. A cut-off of ≥ 6 on total distress score had a high sensitivity (88%) and good specificity (68%) in discriminating between people with UHR/psychosis and individuals without CAARMS diagnosis. With regard to the diagnostic accuracy at the proposed PQ-B cut-off of ≥ 6 on total distress score, sensitivity in our sample (91.4%) was substantially in line with previously reported for the PQ in its various versions. However, this result was much higher to that (62%) observed by Kotzalidis et al. (2017) in the validation study of the Italian version of the 92-item PQ. Moreover, at the proposed PQ-B cut-off of ≥ 6, our PPV (51.2%) was consistent with previously reported, with values ranging between 29% and 44%.

In particular, PPV was equal to 38% in the validation study of the Italian version of the 92-item PQ. The difference between these findings may be the result of differences in selection procedures. In fact, first screening procedure in the ReARMS protocol included a triage service using the SS for psychosis, which probably excluded a certain amount of true negative cases. In our sample, specificity (approximately 25%) was lower than previously reported. Indeed, specificity values were good to excellent in the original study validating the PQ-B at a cut-off of ≥ 6 on total distress score and in the validation study of the Italian version of the 92-item PQ (68% and 82%, respectively). Likewise, our NPV (approximately 77%) was good, but slightly lower than previously reported, with values ranging between 90% and 100%.

In this regards, Kotzalidis et al. (2017) found a NPV of 91% in the validation study of the Italian version of the 92-item PQ. The difference between these findings may be the result of the same differences in selection procedures previously mentioned. However, according to Loewy et al. (2011), for screening purposes, greater weighting should be given to sensitivity over specificity as part of a two-step screening process. Indeed, low sensitivity scores mean that a certain number of people who would appropriate for early intervention are not being identified. Consequently, in most cases, having a few more false positives is less of an issue than missing appropriate individuals from a clinical perspective.
Impact the generalizability of our findings. Indeed, the PQ would ideally be used as the first step in a 2-stage screening process. Therefore, by excluding a certain amount of true negative cases in the pre-PQ step, this would reduce the specificity of the screener. Finally, although the ability of the iPQ-16 to include cases would reduce the specificity of the screener, it may still miss some cases worthy of further investigation. In this respect, Loewy et al. (2011) included 4-point scale questions on distress following each PQ-B item to examine if this enhanced the PPV of the instrument.

Conclusions

The Italian version of the PQ-B showed satisfying psychometric properties, comparable to 92-item homologue. However, yet optimal cut-off to improve concurrent validity and, consequently, economic and clinical usefulness has still to be determined through multi-centric testing. Moreover, the iPQ-B seems to be a suitable screening tool for routine use in mental health care services. Indeed, it is short (taking only few minutes to be completed) and therefore easy to implement in routine assessment. Finally, the iPQ-B can be helpful in identifying potential psychotic symptoms for further exploration in an early phase, especially in young adults and adolescents with low functioning.

Acknowledgements

The current study received no specific grant or other funding from any funding agency, commercial or not-for-profit sector. It also had no relationship that may pose conflict of interest. The authors have no competing interests. ReARMS project is partly financed through a special regional fund: “Progetto Esordi Psicotici della Regione Emilia Romagna”. Our special thanks go to all the staff and service users of all the outpatient community mental health services of the Reggio Emilia Department of Mental Health and Pathological Addiction.
